SAME NAME, DIFFERENT MODEL

One model name, many different models

Every provider compresses the weights its own way

LLAMA-3.3-70B ON OPENROUTER

62x

spread in max output tokens

2048 vs 128000 across 11 endpoints

WHAT THEY DO TO THE WEIGHTS

- BF16 to FP8 to NVFP4 to INT4
- KV cache quantized by a separate flag
- pruning and distillation: a third off
- speculative decoding: a draft module

WHAT IT COSTS YOU

- FP8 on a 70B model: 0.38% MMLU
- int4 under 10B params: minus 5.7%
- NVFP4 KV cache: 6.5 pts on 128k
- int4 under load is slower than BF16

SAME FORMAT, DIFFERENT RECIPE

On GLM-5.2 the same FP4
scores both 100%
and 73% accuracy

it is the calibration and KV cache, not the format

TAKEAWAY

Pin your provider and log it — just like temperature
