

GOOGLE AX

Kubernetes for agent fleets

Not a framework — a control plane for
agentic workloads

THE PROBLEM IT SOLVES

- an agent in a loop burns money all night
- it writes and runs code, so it needs a sandbox
- every framework reinvents that setup
- and nothing can pause a running agent

HOW IT WORKS

- three YAML manifests instead of code
- Task, Workspace, Model — then `ax apply`
- an agent is just an image and a command
- a metadata server answers it over `curl`

SCALE

12.3k 

in the week after launch

Apache-2.0, Go, still v1alpha1

WHAT YOU ACTUALLY GET

- ax suspend and ax resume checkpoints
- a process snapshot, not a step replay
- ax ssh straight into the sandbox
- a goal sentence instead of bootstrap scripts

THE HONEST TRADE-OFF

The code ships exactly one
model provider — Gemini.
And it needs Kubernetes.

MORE

**One agent? Overkill.
A hundred? You'd build
this yourself, worse**
